# 0.1 Indexing in Pandas

Pandas is a Python module that lets us work in a table-like structure called DataFrames. Pandas is the premier module for working with data in Python, and shares may structural similarites to Excel.

```
[13]:
     import pandas as pd
[14]: sales = pd.read_csv('supermarket_sales.csv')
      sales.head()
[14]:
          Invoice ID Branch
                                    City Customer type
                                                          Gender
         750-67-8428
                                  Yangon

                                                                        23.2880
                                                                                    8.4
         10:37
                     Ewallet
                               604.17
                                                       4.761905
                                                                        30.2085
                                                                                    5.3
```

Let's look at the index of the dataframe.

```
[15]: sales.index
```

[15]: RangeIndex(start=0, stop=1000, step=1)

As you can see, the index ranges from 0 to 1000. Let's set the index to something more useful.

Notice that we have to specify the 'inplace' = True keyword to ensure that the change is made in place.

Now the index shows invoices.

#### 0.1.1 Using loc and iloc.

We can access specific columns through the loc and iloc accesors. Loc is used when selecting indexes by name and iloc when accessing indexes by number.

```
[18]: ## Set index to date
      sales.set_index('Date', inplace = True)
[20]: ## Get all sales on Jan. 5, 2019
      sales.loc['1/5/2019']
[20]:

→Index'> with these indexers [3] of <class 'int'>
```

Again, this won't work. The general rule is loc for specific index names and iloc for integer values. If we reset the index, then both loc and iloc will agree with each other.

```
[26]: sales.reset_index(inplace = True)
sales.loc[3]
```

Gender	Male

Rating	8.4
Name: 3, dtype: object	

Note how this looks like a 1D array (called a series in Pandas). Accessing this array is similar to accessing values in a dictionary.

```
[28]: sales.iloc[3]['City']
```

## [28]: 'Yangon'

We can also get all rows of a certain type even if the column isn't the index. Let's get all orders from the city 'Yangon'.

```
[30]: sales.City == 'Yangon'
[30]: 0
               True
      1
             False
      2
               True
      3
               True
      4
               True
      995
             False
      996
             False
      997
               True
      998
               True
      999
               True
      Name: City, Length: 1000, dtype: bool
```

Notice how this only gives us a series of boolean (True or False) values. That's not what we want. Let's use this to index into our original dataframe.

```
[31]: sales.loc[sales.City == 'Yangon']
[31]:
            index

[340 rows x 17 columns]

Now, let's find the sum of all taxes collected on credit card purchases of fashion accesorries. Assume a tax rate of 10%.

```
[35]: ### Get all rows that purchased fashion accessories. Store it into sales_fashion.

sales_fashion = sales[sales['Product line'] == 'Fashion accessories']
```

```
[37]: ### Get all credit card purcahses from sales_fashion.

sales_card_fashion = sales_fashion[sales_fashion['Payment'] == 'Credit card']
```

```
